How to cope with missing data?

strategy 1:

▶ drop rows or columns with missing data
strategy 1:

▶ drop rows or columns with missing data

how well would this work for

▶ weather data
▶ survey data
▶ purchase/click/like data
▶ drug trial
How to cope with missing data?

strategy 2:

- fill in missing entries with row or column mean
How to cope with missing data?

strategy 2:

▶ fill in missing entries with row or column mean

how well would this work for

▶ weather data
▶ survey data
▶ purchase/click/like data
▶ drug trial
strategy 3:

▶ use other columns to predict missing entries
How to cope with missing data?

strategy 3:

▶ use other columns to **predict** missing entries

how well would this work for

▶ weather data
▶ survey data
▶ purchase/click/like data
▶ drug trial
How to cope with missing data?

strategy 3:

▶ use other columns to **predict** missing entries

how well would this work for

▶ weather data
▶ survey data
▶ purchase/click/like data
▶ drug trial

problem: what if **all columns** have (some) missing data?
strategy 4:

- simultaneously learn regression coefficients and covariates to predict every entry in data well

this is such a weird idea that we will need new terminology:

- we no longer can divide the data into inputs and outputs, or features and labels, or covariates and responses
- all we have are some features for each example
- this setting is called unsupervised
Data table

$n$ examples (patients, respondents, households, assets)

$d$ features (tests, questions, sensors, times)

\[
\begin{bmatrix}
Y \\
\end{bmatrix} = \begin{bmatrix}
Y_{11} & \cdots & Y_{1d} \\
\vdots & \ddots & \vdots \\
Y_{n1} & \cdots & Y_{nd}
\end{bmatrix}
\]

- $i$th row of $Y$ is feature vector for $i$th example
- $j$th column of $Y$ gives values for $j$th feature across all examples

Clustering
Low rank model

given: \( n \times d \) data table \( Y \), \( r \leq n, d \)

find: \( X \in \mathbb{R}^{n \times r} \), \( W \in \mathbb{R}^{r \times d} \) for which

\[
\begin{bmatrix}
X \\
W
\end{bmatrix} \approx \begin{bmatrix}
Y
\end{bmatrix}
\]

i.e., \( x_i^T w_j \approx Y_{ij} \), where

\[
X = \begin{bmatrix}
\ldots \\
_\vdots \\
\ldots
\end{bmatrix}
\]

\[
W = \begin{bmatrix}
w_1 \\
\ldots \\
w_d
\end{bmatrix}
\]

interpretation:

- \( r = \text{Rank}(XW) \) is the rank of the model
- \( X \) and \( W \) are (compressed) representation of \( Y \)
- \( x_i \in \mathbb{R}^r \) is a point associated with example \( i \)
- \( w_j \in \mathbb{R}^r \) is a point associated with feature \( j \)
- inner product \( x_i w_j \) approximates \( Y_{ij} \)
Exact low rank fitting

**simplest case:** suppose $Y \in \mathbb{R}^{n \times d}$ has no missing entries

**Q:** what is the smallest $r$ so that

$$Y = XW$$

for $X \in \mathbb{R}^{n \times r}$, $W \in \mathbb{R}^{r \times d}$?

($XW$ is called a **factorization** of $Y$)
Exact low rank fitting

**simplest case:** suppose $Y \in \mathbb{R}^{n \times d}$ has no missing entries

**Q:** what is the smallest $r$ so that

$$Y = XW$$

for $X \in \mathbb{R}^{n \times r}$, $W \in \mathbb{R}^{r \times d}$?

($XW$ is called a **factorization** of $Y$)

**A:** $r = \text{Rank}(Y)$!
Exact low rank fitting

**Theorem:** For $Y \in \mathbb{R}^{n \times d}$,

$$\text{Rank}(Y) = \min\{r : Y = XW, \ X \in \mathbb{R}^{n \times r}, \ W \in \mathbb{R}^{r \times d}\}$$
**Exact low rank fitting**

**Theorem:** For $Y \in \mathbb{R}^{n \times d}$,

$$\text{Rank}(Y) = \min \{ r : Y = XW, \quad X \in \mathbb{R}^{n \times r}, \; W \in \mathbb{R}^{r \times d} \}$$

**Proof:**

1) We can find $X$ and $W$ with $Y = XW$ and $r = \text{Rank}(Y)$:

- Suppose $Y = U\Sigma V^T$ is the skinny SVD of $Y$.
- Then $\text{Rank}(Y) =$ number of columns of $U$ and of $V$.
- Let $X = U$, $W = \Sigma V^T$.
- Then $Y = XW$.
Exact low rank fitting

**Theorem:** For $Y \in \mathbb{R}^{n \times d}$,

$$\text{Rank}(Y) = \min \{ r : Y = XW, \quad X \in \mathbb{R}^{n \times r}, \ W \in \mathbb{R}^{r \times d} \}$$

**Proof:**

1) We can find $X$ and $W$ with $Y = XW$ and $r = \text{Rank}(Y)$:

- Suppose $Y = U \Sigma V^T$ is the skinny SVD of $Y$
- Then $\text{Rank}(Y) =$ number of columns of $U$ and of $V$
- Let $X = U$, $W = \Sigma V^T$
- Then $Y = XW$

2) For any $X$ and $W$ st $Y = XW$, $\text{Rank}(Y) \leq r$:

- $\text{Rank}(Y) = \text{Rank}(XW) \leq \min(\text{Rank}(X), \text{Rank}(W)) \leq r$
Exact low rank fitting

**Theorem:** for $Y \in \mathbb{R}^{n \times d}$,

$$\text{Rank}(Y) = \min\{r : Y = XW, \quad X \in \mathbb{R}^{n \times r}, \quad W \in \mathbb{R}^{r \times d}\}$$

**Proof:** 1) we can find $X$ and $W$ with $Y = XW$ and $r = \text{Rank}(Y)$:

- suppose $Y = U\Sigma V^T$ is the skinny SVD of $Y$
- then $\text{Rank}(Y) = \text{number of columns of } U \text{ and of } V$
- let $X = U$, $W = \Sigma V^T$
- then $Y = XW$

2) for any $X$ and $W$ st $Y = XW$, $\text{Rank}(Y) \leq r$:

- $\text{Rank}(Y) = \text{Rank}(XW) \leq \min(\text{Rank}(X), \text{Rank}(W)) \leq r$

so $\text{Rank}(Y)$ is the smallest $r$ st $Y = XW$
if we’re willing to represent $Y$ approximately, can we use a smaller rank $r$?

Clustering
Principal components analysis (PCA)
**Principal components analysis (PCA)**

**Principal components analysis (PCA):** Given $Y \in \mathbb{R}^{n \times d}$, solve

$$\text{minimize} \quad \| Y - XW \|_F^2 = \sum_{i=1}^{m} \sum_{j=1}^{n} (Y_{ij} - x_i^T w_j)^2$$

with $X \in \mathbb{R}^{n \times r}$, $W \in \mathbb{R}^{r \times d}$

- a very old problem (Pearson 1901, Hotelling 1933)
- least squares low rank fitting

**notice:** objective depends only on product $XW$, so if $(X, W)$ is a solution, so is $(\tilde{X}, \tilde{W}) = (XT, T^{-1}W)$ for any invertible matrix $T \in \mathbb{R}^{r \times r}$:

$$\tilde{X} \tilde{W} = XTT^{-1}W = XW.$$
Principal components analysis (PCA)

Principal components analysis (PCA): Given $Y \in \mathbb{R}^{n \times d}$, solve

$$\minimize \quad \|Y - XW\|_F^2 = \sum_{i=1}^m \sum_{j=1}^n (Y_{ij} - x_i^T w_j)^2$$

with $X \in \mathbb{R}^{n \times r}$, $W \in \mathbb{R}^{r \times d}$

- a very old problem (Pearson 1901, Hotelling 1933)
- least squares low rank fitting

notice: objective depends only on product $XW$, so if $(X, W)$ is a solution, so is $(\tilde{X}, \tilde{W}) = (XT, T^{-1}W)$ for any invertible matrix $T \in \mathbb{R}^{r \times r}$:

$$\tilde{X}\tilde{W} = XTT^{-1}W = XW.$$ 

make sure *interpretation* of solution is invariant under $T$
PCA finds best covariates

example with \( d = 2, \ r = 1 \)

**regression:** fix \( X = Y_{:,1} \) (first column of \( Y \)), solve

\[
\text{minimize} \quad \| Y - XW \|_F^2 \quad \text{wrt variable} \quad W \in \mathbb{R}^{1 \times 2}
\]
PCA finds best covariates

example with $d = 2$, $r = 1$

**PCA**: solve

$$\text{minimize } \| Y - XW \|_F^2 \quad \text{wrt variables } X \in \mathbb{R}^{n \times 1}, W \in \mathbb{R}^{1 \times 2}$$
On lines and planes of best fit
Low rank models for gait analysis

Principal components analysis (PCA): Given $Y \in \mathbb{R}^{n \times d}$, solve

$$\text{minimize} \quad \|Y - XW\|^2_F = \sum_{i=1}^n \sum_{j=1}^d (Y_{ij} - x_i^T w_j)^2$$

with $X \in \mathbb{R}^{n \times r}$, $W \in \mathbb{R}^{r \times d}$

how should we solve this problem?
Principal components analysis (PCA)

Given \( Y \in \mathbb{R}^{n \times d} \), solve

\[
\text{minimize} \quad \| Y - XW \|_F^2 = \sum_{i=1}^{n} \sum_{j=1}^{d} (Y_{ij} - x_i^T w_j)^2
\]

with \( X \in \mathbb{R}^{n \times r} \), \( W \in \mathbb{R}^{r \times d} \)

how should we solve this problem?

- idea 1: use the SVD
- idea 2: alternating minimization over \( X \) and \( W \)
The Frobenius norm

the Frobenius norm

\[ \|A\|_F = \sqrt{\sum_{i=1}^{n} \sum_{j=1}^{d} A_{ij}^2} \]

some useful identities:

- \( \|A\|_F = \|\text{vec}(A)\| \)
- \( \|A\|_F = \|A^T\|_F \)
- \( \|A\|^2_F = \text{tr}(A^T A) \)
- if \( U \) is orthogonal (i.e., \( U^T U = I \)), then \( \|UA\|_F = \|A\|_F \)
The Frobenius norm

the **Frobenius norm**

\[
\|A\|_F = \sqrt{\sum_{i=1}^{n} \sum_{j=1}^{d} A_{ij}^2}
\]

some useful identities:

- \( \|A\|_F = \|\text{vec}(A)\| \)
- \( \|A\|_F = \|A^T\|_F \)
- \( \|A\|_F^2 = \text{tr}(A^T A) \)
- if \( U \) is orthogonal (i.e., \( U^T U = I \)), then \( \|UA\|_F = \|A\|_F \)

**proof:**

\[
\|UA\|_F^2 = \text{tr}((UA)^T UA) = \text{tr}(A^T U^T UA) = \text{tr}(A^T A) = \|A\|_F^2
\]
PCA: solution via the SVD

**PCA:** with $X \in \mathbb{R}^{n \times r}$, $W \in \mathbb{R}^{r \times d}$, solve

$$\text{minimize } \| Y - XW \|_F^2 = \sum_{i=1}^{m} \sum_{j=1}^{n} (Y_{ij} - x_i^T w_j)^2$$

**Eckart-Young-Mirsky theorem:** if

$$Y = U \Sigma V^T = \sum_{i=1}^{\text{Rank}(Y)} \sigma_i u_i v_i^T$$

is the SVD of $Y$, then

$$X = U_r, \quad W = \Sigma_r V_r^T$$

is a solution to PCA, where

$$\Sigma_r = \text{diag}(\sigma_1, \ldots, \sigma_r), \quad U_r = [u_1 \cdots u_r], \quad V_r = [v_1 \cdots v_r].$$
PCA: solution via the SVD

**PCA:** with $X \in \mathbb{R}^{n \times r}$, $W \in \mathbb{R}^{r \times d}$, solve

$$\text{minimize } \| Y - XW \|_F^2 = \sum_{i=1}^m \sum_{j=1}^n (Y_{ij} - x_i^T w_j)^2$$

**Eckart-Young-Mirsky theorem:** if

$$Y = U \Sigma V^T = \sum_{i=1}^{\text{Rank}(Y)} \sigma_i u_i v_i^T$$

is the SVD of $Y$, then

$$X = U_r, \quad W = \Sigma_r V_r^T$$

is a solution to PCA, where

$$\Sigma_r = \text{diag}(\sigma_1, \ldots, \sigma_r), \quad U_r = [u_1 \cdots u_r], \quad V_r = [v_1 \cdots v_r].$$

with this $X$ and $W$,

$$\| Y - XW \|_F^2 = \| U \Sigma V^T - U_r \Sigma_r V_r^T \|_F^2 = \sum_{i=r+1}^{\text{Rank}(Y)} \sigma_i^2$$
Proof of Eckart-Young-Mirsky theorem I

proof step 1: reduce to diagonal.
if \( Y = U\Sigma V^T \) is the full SVD, then

\[
U^T U = UU^T = I \quad \text{and} \quad V^T V = VV^T = I,
\]

so

\[
\| Y - XW \|_F^2 = \| U\Sigma V^T - XW \|_F^2 \\
= \| U^T U\Sigma V^T V - U^T XWV \|_F^2 \\
= \| \Sigma - U^T XWV \|_F^2 \\
= \| \Sigma - Z \|_F^2
\]

where \( Z = U^T XWV \) is a rank \( r \) matrix.
we want to show

\[
\sum_{i=r+1}^{\text{Rank}(Y)} \sigma_i \leq \| \Sigma - Z \|_F^2
\]

for any rank \( r \) matrix \( Z \).
Proof of Eckart-Young-Mirsky theorem II

proof step 2: eigenvalue interlacing.
let’s use Weyl’s theorem for eigenvalues:
for any matrices $A, B \in \mathbb{R}^{n \times d}$,

$$\sigma_{i+j-1}(A + B) \leq \sigma_i(A) + \sigma_j(B), \quad 1 \leq i, j \leq n.$$ 

set $A = \Sigma - Z$, $B = Z$, $j = r + 1$ to get

$$\sigma_{i+r}(\Sigma) \leq \sigma_i(\Sigma - Z) + \sigma_{r+1}(Z), \quad 1 \leq i \leq n - r$$

$$\sigma_{i+r} \leq \sigma_i(\Sigma - Z), \quad 1 \leq i \leq n - r,$$

using $\text{Rank}(Z) \leq r$. square and sum from $i = 1$ to $\text{Rank}(Y) - r$:

$$\|\Sigma - \Sigma_r\|_F^2 = \sum_{i=r+1}^{\text{Rank}(Y)} \sigma_i^2 \leq \sum_{i=1}^{\text{Rank}(Y) - r} \sigma_i^2(\Sigma - Z) \leq \|\Sigma - Z\|_F^2.$$
PCA: solution via AM

\[
\text{minimize} \quad \| Y - XW \|_F^2 = \sum_{i=1}^{m} \sum_{j=1}^{n} (Y_{ij} - x_i^T w_j)^2
\]

**Alternating Minimization (AM):** fix \( W^0 \). for \( t = 1, \ldots, \)

\[ X^t = \arg\min_X \| Y - XW^{t-1} \|_F^2 \]
\[ W^t = \arg\min_W \| Y - X^t W \|_F^2 \]

**Properties:**

- objective decreases at each iteration
- objective bounded below, so the procedure converges
- (it is true but we won’t prove that) with probability 1 over choices of \( W^0 \), AM converges to an optimal solution
how would you solve the AM subproblem

$$W^t = \arg\min_W \| Y - X^t W \|_F^2 = \arg\min_W \sum_{j=1}^d \| y_j - X^t w_j \|^2$$

where $Y = [y_1 \cdots y_d]$, $W = [w_1 \cdots w_d]$?
PCA: AM subproblem is separable

how would you solve the AM subproblem

\[ W^t = \arg\min_W \| Y - X^t W \|_F^2 = \arg\min_W \sum_{j=1}^d \| y_j - X^t w_j \|_2^2 \]

where \( Y = [y_1 \cdots y_d] \), \( W = [w_1 \cdots w_d] \)?

▶ problem separates over columns of \( W \):

\[ w_j^t = \arg\min_w \| y_j - X^t w \|_2^2 \]

▶ for each column of \( W \), it’s just a least squares problem!

\[ w_j = ((X^t)^T X^t)^{-1} (X^t)^T y_j \]
PCA: solution via AM

\[ \text{minimize} \quad \| Y - XW \|_F^2 = \sum_{i=1}^{n} \sum_{j=1}^{d} (Y_{ij} - x_i^T w_j)^2 \]

**Alternating Minimization (AM):** fix $W^0$. for $t = 1, \ldots,$

- for $i = 1, \ldots, n$,
  \[ x_i^t = Y_i : (W^{t-1})^T (W^{t-1} (W^{t-1})^T)^{-1} \]

- for $j = 1, \ldots, d$,
  \[ w_j^t = ((X^t)^TX^t)^{-1}(X^t)^T y_j \]
PCA: solution via AM

minimize  \[ \| Y - XW \|_F^2 = \sum_{i=1}^{n} \sum_{j=1}^{d} (Y_{ij} - x_i^T w_j)^2 \]

computational tricks:

- cache gram matrix \( G = (X^t)^T X^t \)
- parallelize over \( j \)

**Alternating Minimization (AM):** fix \( W^0 \). for \( t = 1, \ldots, \)

- cache factorization of \( G = W^{t-1}(W^{t-1})^T \)
- in parallel, for \( i = 1, \ldots, n, \)
  \[ x_i^t = Y_i : (W^{t-1})^T (W^{t-1}(W^{t-1})^T)^{-1} \]

- cache factorization of \( G = (X^t)^T X^t \)
- in parallel, for \( j = 1, \ldots, d, \)
  \[ w_j^t = ((X^t)^T X^t)^{-1}(X^t)^T y_j \]
PCA: solution via AM

\[
\text{minimize } \| Y - XW \|_F^2 = \sum_{i=1}^{m} \sum_{j=1}^{n} (Y_{ij} - x_i^T w_j)^2
\]

complexity?

**Alternating Minimization (AM):** fix \( W^0 \). for \( t = 1, \ldots, \)
PCA: solution via AM

\[
\text{minimize} \quad \| Y - XW \|_F^2 = \sum_{i=1}^m \sum_{j=1}^n (Y_{ij} - x_i^T w_j)^2
\]

complexity?

**Alternating Minimization (AM):** fix \( W^0 \). for \( t = 1, \ldots \),

- cache factorization of \( G = W^{t-1}(W^{t-1})^T \) \((O(dr^2 + r^3))\)
PCA: solution via AM

minimize $\| Y - XW \|_F^2 = \sum_{i=1}^m \sum_{j=1}^n (Y_{ij} - x_i^T w_j)^2$

complexity?

**Alternating Minimization (AM):** fix $W^0$. for $t = 1, \ldots,$

- cache factorization of $G = W^{t-1}(W^{t-1})^T$ ($O(dr^2 + r^3)$)
- in parallel, for $i = 1, \ldots, n$,

$$x_i^t = (W^{t-1}(W^{t-1})^T)^{-1} W^{t-1} Y_{i:}$$
PCA: solution via AM

minimize \[ \| Y - XW \|_F^2 = \sum_{i=1}^{m} \sum_{j=1}^{n} (Y_{ij} - x_i^T w_j)^2 \]

complexity?

**Alternating Minimization (AM):** fix \( W^0 \). for \( t = 1, \ldots, \)

- cache factorization of \( G = W^{t-1}(W^{t-1})^T \) \((O(dr^2 + r^3))\)
- in parallel, for \( i = 1, \ldots, n \),
  \[
  x_i^t = (W^{t-1}(W^{t-1})^T)^{-1} W^{t-1} Y_i^T
  \]

- cache factorization of \( G = (X^t)^T X^t \) \((O(nr^2 + r^3))\)
PCA: solution via AM

minimize $\| Y - XW \|_F^2 = \sum_{i=1}^{m} \sum_{j=1}^{n} (Y_{ij} - x_i^T w_j)^2$

complexity?

**Alternating Minimization (AM):** fix $W^0$. for $t = 1, \ldots$,

- cache factorization of $G = W^{t-1}(W^{t-1})^T$ $(\mathcal{O}(dr^2 + r^3))$
- in parallel, for $i = 1, \ldots, n$,
  $$x_i^t = (W^{t-1}(W^{t-1})^T)^{-1}W^{t-1}Y_i^T$$

- cache factorization of $G = (X^t)^TX^t$ $(\mathcal{O}(nr^2 + r^3))$
- in parallel, for $j = 1, \ldots, d$,
  $$w_j^t = ((X^t)^TX^t)^{-1}(X^t)^Ty_j$$

- pca
Generalized low rank models

minimize \[ \sum_{(i,j) \in \Omega} \ell_j(Y_{ij}, x_i^T w_j) + \sum_{i=1}^n r_i(x_i) + \sum_{j=1}^d \tilde{r}_j(w_j) \]

- observe only \((i, j) \in \Omega\) (other entries are missing)
- loss functions \(\ell_j\) for each column
  - assume \(Y_{ij} \in \mathcal{Y}_j\) for every \((i, j) \in \Omega\)
  - \(\ell_j : \mathcal{Y}_j \times \mathbb{R} \rightarrow \mathbb{R}\)
  - e.g., different losses for reals, booleans, categoricals, ordinals, ...
- regularizers \(r : \mathbb{R}^{1 \times r} \rightarrow \mathbb{R}, \tilde{r} : \mathbb{R}^r \rightarrow \mathbb{R}\)
Losses

minimize \[ \sum_{(i,j) \in \Omega} L_j(x_i y_j, A_{ij}) + \sum_{i=1}^{m} r_x(x_i) + \sum_{j=1}^{n} r_y(y_j) \]

choose loss \( L : \mathbb{R} \times \mathcal{F} \to \mathbb{R} \) adapted to data type \( \mathcal{F} \):

<table>
<thead>
<tr>
<th>data type</th>
<th>loss</th>
<th>( L(u, a) )</th>
</tr>
</thead>
<tbody>
<tr>
<td>real</td>
<td>QuadLoss</td>
<td>( (u - a)^2 )</td>
</tr>
<tr>
<td>real</td>
<td>L1Loss</td>
<td>(</td>
</tr>
<tr>
<td>real</td>
<td>HuberLoss</td>
<td>( \text{huber}(u - a) )</td>
</tr>
<tr>
<td>boolean</td>
<td>HingeLoss</td>
<td>( (1 - ua)_+ )</td>
</tr>
<tr>
<td>boolean</td>
<td>LogisticLoss</td>
<td>( \log(1 + \exp(-au)) )</td>
</tr>
<tr>
<td>ordinal</td>
<td>BvSLoss</td>
<td>( \sum_{a' = 1}^{d} (1 - u(a \geq a'))_+ )</td>
</tr>
<tr>
<td>ordinal</td>
<td>OrdinalHingeLoss</td>
<td>( \sum_{a'=1}^{a-1} (1 - u + a')<em>+ + \sum</em>{a' = a+1}^{d} (1 + u - a')_+ )</td>
</tr>
<tr>
<td>categorical</td>
<td>OvALoss</td>
<td>( (1 - u_a)<em>+ + \sum</em>{a' \neq a} (1 + u_{a'})_+ )</td>
</tr>
<tr>
<td>categorical</td>
<td>MultinomialLoss</td>
<td>( \frac{\exp(u_a)}{\sum_{a'=1}^{d} \exp(u_{a'})} )</td>
</tr>
</tbody>
</table>
Regularizers

minimize \( \sum_{(i,j) \in \Omega} L_j(x_i y_j, A_{ij}) + \sum_{i=1}^m r_x(x_i) + \sum_{j=1}^n r_y(y_j) \)

choose regularizers \( r_x, r_y \) to impose structure:

<table>
<thead>
<tr>
<th>structure</th>
<th>( r_x )</th>
<th>( r_y )</th>
</tr>
</thead>
<tbody>
<tr>
<td>small</td>
<td>QuadReg</td>
<td>QuadReg</td>
</tr>

</tr>
<tr>
<td>nonnegative</td>
<td>NonNegConstraint</td>
<td>NonNegConstraint</td>
</tr>
<tr>
<td>clustered</td>
<td>UnitOneSparseConstraint</td>
<td>ZeroReg</td>
</tr>
</tbody>
</table>
Impute missing data

impute most likely true data $\hat{A}_{ij}$

$$\hat{A}_{ij} = \arg\min_a L_j(x_iy_j, a)$$

- implicit constraint: $\hat{A}_{ij} \in F_j$
- when $L_j$ is quadratic, $\ell_1$, or Huber loss, then $\hat{A}_{ij} = x_iy_j$
- if $F \neq \mathbb{R}$, $\arg\min_a L_j(x_iy_j, a) \neq x_iy_j$
  - e.g., for hinge loss $L(u, a) = (1 - ua)_+$, $\hat{A}_{ij} = \text{sign}(x_iy_j)$

can we predict 10 more +s?
Impute censored data

The graph shows the relationship between the probability of +1 and the regularization parameter. The precision@10 is calculated for different values of the regularization parameter, ranging from 0 to 40. The graph indicates an increasing trend in precision@10 as the regularization parameter increases.
Outline

Missing data
Unsupervised learning
Low rank models
Principal Components Analysis
Generalized Low Rank Models
Imputing missing data
Multidimensional losses
More about regularizers
Clustering
Multi-dimensional loss

- approximate using vectors $x_i W_j \in \mathbb{R}^{1 \times d_j}$ instead of numbers
- need $\ell_j : \mathbb{R}^{1 \times d_j} \times \mathcal{Y}_j \rightarrow \mathbb{R}$

$$\text{minimize} \quad \sum_{(i,j) \in \Omega} \ell_j(x_i W_j, Y_{ij}) + \sum_{i=1}^{m} r_i(x_i) + \sum_{j=1}^{n} \tilde{r}_j(W_j)$$

- useful for approximating **categorical** variables
  - columns of $W_j$ represent different labels of categorical variable
- gives more flexible/accurate models for **ordinal** variables
Multivariate categorical loss

▶ choose any loss function for multiclass classification to penalize $x_i, Y$
  ▶ e.g., one-vs-all (elementwise hinge loss) [Rifkin 2004]

$$\ell(z, y) = (1 - z_y)_+ + \sum_{y' \neq y} (1 + z_{y'})_+$$
Multivariate ordinal loss

- automatically detect which labels are more similar
- fit positions of data ($X$) and separating hyperplanes ($W$) simultaneously
Scaling losses

Analogue of standardization for GLRM:

\[
\mu_j = \arg\min_{\mu} \sum_{i: (i, j) \in \Omega} \ell_j(\mu, Y_{ij})
\]

\[
\sigma^2_j = \frac{1}{n_j - 1} \sum_{i: (i, j) \in \Omega} \ell_j(\mu_j, Y_{ij})
\]

- \(n_j\) is number of observations in column \(j\)
- \(\mu_j\) generalizes column mean
- \(\sigma^2_j\) generalizes column variance

To fit a standardized GLRM, solve

\[
\text{minimize} \quad \sum_{(i, j) \in \Omega} \frac{\ell_j(Y_{ij}, x_i W_j + \mu_j)}{\sigma^2_j} + \sum_{i=1}^{n} r_i(x_i) + \sum_{j=1}^{d} \tilde{r}_j(W_j)
\]
Scaling losses

Analogue of standardization for GLRM:

\[ \mu_j = \text{argmin}_\mu \sum_{i:(i,j)\in\Omega} \ell_j(\mu, Y_{ij}) \]
\[ \sigma_j^2 = \frac{1}{n_j - 1} \sum_{i:(i,j)\in\Omega} \ell_j(\mu_j, Y_{ij}) \]

- \( n_j \) is number of observations in column \( j \)
- \( \mu_j \) generalizes column mean
- \( \sigma_j^2 \) generalizes column variance

To fit a standardized GLRM, solve

\[
\text{minimize} \quad \sum_{(i,j)\in\Omega} \frac{\ell_j(Y_{ij}, x_i W_j + \mu_j)}{\sigma_j^2} + \sum_{i=1}^n r_i(x_i) + \sum_{j=1}^d \tilde{r}_j(W_j)
\]

can be put in standard form: add an offset by modifying \( r \)!
American community survey

2013 ACS:

- 3M respondents, 87 economic/demographic survey questions
  - income
  - cost of utilities (water, gas, electric)
  - weeks worked per year
  - hours worked per week
  - home ownership
  - looking for work
  - use foodstamps
  - education level
  - state of residence
  - ...

- 1/3 of responses missing
Application: exploratory data analysis

Fitting a GLRM to the ACS

- construct a rank 10 GLRM with loss functions respecting data types
  - huber for real values
  - hinge loss for booleans
  - ordinal hinge loss for ordinals
  - one-vs-all hinge loss for categoricals
- scale losses and regularizers
- fit the GLRM

in 2 lines of code:

```python
glrm, labels = GLRM(Y, 10, scale = true)
X,W = fit!(glrm)
```
American community survey

most similar features (in demography space):

- Alaska: Montana, North Dakota
- California: Illinois, cost of water
- Colorado: Oregon, Idaho
- Ohio: Indiana, Michigan
- Pennsylvania: Massachusetts, New Jersey
- Virginia: Maryland, Connecticut
- Hours worked: weeks worked, education
Low rank models for dimensionality reduction\(^1\)

U.S. Wage & Hour Division (WHD) compliance actions:

Nonnegative matrix factorization

\[
\text{minimize} \quad \sum_{(i,j) \in \Omega} (Y_{ij} - x_i^T w_j)^2 + \sum_{i=1}^{n} \mathbf{1}_+(x_i) + \sum_{j=1}^{d} \mathbf{1}_+(w_j)
\]

- regularizer is indicator of nonnegative orthant

\[
\mathbf{1}_+(x) = \begin{cases} 
0 & x \geq 0 \\
\infty & \text{otherwise}
\end{cases}
\]
Nonnegative matrix factorization

\[
\text{minimize } \sum_{(i,j) \in \Omega} (Y_{ij} - x_i^T w_j)^2 + \sum_{i=1}^{n} 1_+(x_i) + \sum_{j=1}^{d} 1_+(w_j)
\]

- regularizer is indicator of nonnegative orthant

\[
1_+(x) = \begin{cases} 
0 & x \geq 0 \\
\infty & \text{otherwise}
\end{cases}
\]

subproblems are nonnegative least squares problems:

\[
x_i^{t+1} = \arg \min_{x > 0} \sum_{j: (i,j) \in \Omega} (Y_{ij} - x^T w_j^t)^2 \quad (1)
\]

\[
w_j^{t+1} = \arg \min_{w > 0} \sum_{i: (i,j) \in \Omega} (Y_{ij} - (x_i^{t+1})^T w)^2 \quad (2)
\]

More about regularizers

Clustering
Clustering

a **clustering** algorithm groups data points into clusters

examples:

- **medical diagnosis.** cluster patients with similar medical histories
- **topic model.** cluster documents with similar patterns of word usage
- **market segmentation.** cluster customers with similar purchase patterns
the $k$-means problem:

- given data points $y_i \in \mathbb{R}^d$, $i = 1, \ldots, n$
- find $k$ centers $w_l \in \mathbb{R}^d$, $l = 1, \ldots, k$
- and assignments $c_i \in \{1, \ldots, k\}$, $i = 1, \ldots, n$
- to minimize

$$\sum_{i=1}^{n} \| y_i - w_{c_i} \|^2$$
Lloyd’s algorithm for $k$-means

**Lloyd’s algorithm** (aka the $k$-means algorithm): to minimize

$$\sum_{i=1}^{n} \| y_i - w_{c_i} \|^2,$$

repeat

1. assign points to centers

$$c_i = \arg\min_{l=1,\ldots,k} \| y_i - w_l \|^2, \quad i = 1,\ldots,n$$

2. update centers: let $C_l = \{ i : c_i = l \}$ be points assigned to cluster $l$, and set

$$w_l = \frac{1}{|C_l|} \sum_{i \in C_l} y_i, \quad l = 1,\ldots,k$$

visualizing the algorithm:

[http://stanford.edu/class/ee103/visualizations/kmeans/kmeans.html](http://stanford.edu/class/ee103/visualizations/kmeans/kmeans.html)
Lloyd’s algorithm for \( k \)-means

**Lloyd’s algorithm** (aka the \( k \)-means algorithm): to minimize

\[
\sum_{i=1}^{n} \| y_i - w_{c_i} \|^2,
\]

repeat

1. assign points to centers

\[
c_i = \arg\min_{l=1,...,k} \| y_i - w_l \|^2, \quad i = 1, \ldots, n
\]

2. update centers

\[
w_l = \frac{1}{|C_l|} \sum_{i \in C_l} y_i = \arg\min_{l=1,...,k} \sum_{i:c_i=l} \| y_i - w \|^2, \quad l = 1, \ldots, k
\]
Quadratic clustering

minimize \( \sum_{(i,j) \in \Omega} (Y_{ij} x_i^T w_j)^2 + \sum_{i=1}^{n} 1_1(x_i) \)

\( 1_1 \) is the indicator function of a selection, i.e.,

\[
1_1(x) = \begin{cases} 
0 & x = e_l \text{ for some } l \in \{1, \ldots, k\} \\
\infty & \text{otherwise}
\end{cases}
\]

where \( e_l \) is the \( l \)th unit vector
**Quadratic clustering**

\[
\text{minimize } \sum_{(i,j) \in \Omega} (Y_{ij} x_i^T w_j)^2 + \sum_{i=1}^n 1_1(x_i)
\]

- \(1_1\) is the indicator function of a selection, i.e.,

\[
1_1(x) = \begin{cases} 
0 & \text{if } x = e_l \text{ for some } l \in \{1, \ldots, k\} \\
\infty & \text{otherwise}
\end{cases}
\]

where \(e_l\) is the \(l\)th unit vector

**alternating minimization reproduces \(k\)-means**

(but allows missing data)
Check AM reproduces $k$-means

let $w^l$ be $l$th row of $W$, $l = 1, \ldots, k$

$$
\sum_{(i,j)\in\{1,\ldots,n\}\times\{1,\ldots,d\}} (Y_{ij} - x_i^T w_j)^2 = \sum_{l=1}^{k} \sum_{i\in C_l} \sum_{j=1}^{d} (Y_{ij} - x_i^T w_j)^2
$$

$$
= \sum_{l=1}^{k} \sum_{i\in C_l} \sum_{j=1}^{d} (Y_{ij} - e_l w_j)^2
$$

$$
= \sum_{l=1}^{k} \sum_{i\in C_l} \sum_{j=1}^{d} (Y_{ij} - w_j^l)^2
$$

$$
= \sum_{l=1}^{k} \sum_{i\in C_l} \|Y_i - w^l\|^2
$$

$\blacktriangleright$ to minimize over $W$: set $w^l$ to be the mean of $Y_i$ for $i \in C_l$

$$
w^l = \frac{1}{C_l} \sum_{i\in C_l} Y_i$$
Check AM reproduces $k$-means

Let $w^l$ be $l$th row of $W$, $l = 1, \ldots, k$

$$
\sum_{(i,j) \in \{1, \ldots, n\} \times \{1, \ldots, d\}} (Y_{ij} - x_i^T w_j)^2 = \sum_{l=1}^{k} \sum_{i \in C_l} \sum_{j=1}^{d} (Y_{ij} - x_i^T w_j)^2
$$

$$
= \sum_{l=1}^{k} \sum_{i \in C_l} \sum_{j=1}^{d} (Y_{ij} - e_l w_j)^2
$$

$$
= \sum_{l=1}^{k} \sum_{i \in C_l} \sum_{j=1}^{d} (Y_{ij} - w_j^l)^2
$$

$$
= \sum_{l=1}^{k} \sum_{i \in C_l} \|Y_i - w^l\|^2
$$

$\blacktriangleright$ to minimize over $X$: set $x_i$ to be the unit vector $e_l$

$$
x_i = e_l \quad \text{where} \quad l = \arg\min_{l'} 1, \ldots, k \|Y_i - w^{l'}\|^2
$$
What's a cluster?
Modifying $k$-means

different regularizers:

▶ clusters
▶ rays
▶ lines
▶ planes
▶ cones
Modifying $k$-means

different regularizers:

▶ clusters
▶ rays
▶ lines
▶ planes
▶ cones

different losses:

▶ $k$-means: $\ell(y, z) = (y - z)^2$
▶ $k$-medioids: $\ell(y, z) = |y - z|$
▶ $\ell(y, z) = \text{huber}(y - z)$
▶ ...
Fitting GLRMds with alternating minimization

\[
\text{minimize } \sum_{(i,j) \in \Omega} L_j(x_i w_j, Y_{ij}) + \sum_{i=1}^m r_i(x_i) + \sum_{j=1}^n \tilde{r}_j(w_j)
\]

repeat:

1. minimize objective over \( x_i \) (in parallel)
2. minimize objective over \( w_j \) (in parallel)

properties:

- subproblems easy to solve
- objective decreases at every step, so converges if losses and regularizers are bounded below
- (not guaranteed to find global solution, but) usually finds good model in practice
- naturally parallel, so scales to **huge** problems
Alternating updates

given $X^0$, $W^0$

for $t = 1, 2, \ldots$ do

for $i = 1, \ldots, m$ do

$x_i^t = \text{update}_{L,r}(x_i^{t-1}, W^{t-1}, Y)$

for $j = 1, \ldots, n$ do

$w_j^t = \text{update}_{L,\tilde{r}}(w_j^{(t-1)T}, X(t)^T, Y^T)$

- no need to exactly minimize
- choose fast, simple update rules
A simple, fast update rule

proximal gradient method: let

\[ g = \sum_{j:(i,j) \in \Omega} \nabla \ell_j(x_i w_j, Y_{ij}) w_j \]

and update

\[ x_i^{t+1} = \text{prox}_{\alpha t r}(x_i^t - \alpha_t g) \]

- **simple**: only requires ability to evaluate \( \nabla L \) and \( \text{prox}_r \)
- **stochastic variant**: use noisy estimate for \( g \)
- **time per iteration**: \( O\left(\frac{(n+d+|\Omega|)k}{p}\right) \) on \( p \) processors
Recap: GLRM}s

Generalized Low Rank Models are a \textbf{framework} that encompasses a bunch of unsupervised learning models

many of these GLRM}s have names:

\begin{table}[h!]
\centering
\begin{tabular}{|l|l|l|l|l|}
\hline
\textbf{Model} & \textbf{$\ell(y, z)$} & \textbf{$r(x)$} & \textbf{$\tilde{r}(w)$} & \textbf{reference} \\
\hline
PCA & $(y - z)^2$ & 0 & 0 & [Pearson 1901] \\
NNMF & $(y - z)^2$ & $\mathbf{1_+}(x)$ & $\mathbf{1_+}(w)$ & [Lee 1999] \\
sparse PCA & $(y - z)^2$ & $\|x\|_1$ & $\|w\|_1$ & [D’Aspremont 2004] \\
sparse coding & $(y - z)^2$ & $\|x\|_1$ & $\|w\|_2$ & [Olshausen 1997] \\
$k$-means & $(y - z)^2$ & $\mathbf{1_1}(x)$ & 0 & [Tropp 2004] \\
matrix completion & $(y - z)^2$ & $\|x\|_2$ & $\|w\|_2$ & [Keshavan 2010] \\
robust PCA & $|y - z|$ & $\|x\|_2$ & $\|w\|_2$ & [Candes 2011] \\
logistic PCA & $\log(1 + \exp(-yz))$ & $\|x\|_2$ & $\|w\|_2$ & [Collins 2001] \\
boolean PCA & $(1 - yz)_+$ & $\|x\|_2$ & $\|w\|_2$ & [Srebro 2004] \\
\hline
\end{tabular}
\end{table}
